

Water Footprinting and other Agricultural SaaS Solutions

ecometrica

bringing clarity

*Bertil Abbing
Head of UK Sustainability Analysts*

Ecometrica

is an end-to-end environmental software-as-a-service (SaaS) provider that is recognized as one of the world's top Sustainability brands.

We have unrivalled experience in helping businesses and governments identify risks and opportunities by combining satellite earth observation data with local information and business intelligence on the award-winning Ecometrica Platform.

Ecometrica brings together recognized experts in environmental and sustainability accounting, and our software supports all aspects of sustainability planning, operations and reporting.

Our data and software services are available worldwide through our offices in London, Boston, Edinburgh and Montreal.

Content

- Benefits of SaaS
- Waterfoot Printing
- Land Use and Land Use Change (LULUC)
- Soil Moisture Change
- Water Risk and Drought Vulnerability

Benefits of SaaS

- No tedious spreadsheet calculations
- Increased accuracy
- Accessibility
- Cloud based - No software installation
- Automatic updates on a timely basis
- Increased data analysis and results
- No maintenance cost
- No capital expenses

Water footprinting Methodology

The Water Footprint Assessment Manual (Hoekstra A.Y., et al. 2011)
Grey Water Footprint Accounting (Franke N.A., et al. 2013)

What is a water footprint?

The water footprint measures the amount of water used to produce each of the goods and services we use. It can be measured for a single process, such as growing rice, for a product, such as a pair of jeans, for the fuel we put in our car, or for an entire multi-national company. The water footprint can also tell us how much water is being consumed by a particular country – or globally – in a specific river basin or from an aquifer.

Source: <http://waterfootprint.org>

Water footprinting Calculations

$$WF_{proc,green} = \textit{GreenWaterEvaporation} + \textit{GreenWaterIncorporation}$$

[volume/time]

$$WF_{proc,green} = \frac{CWU_{green}}{Y} \quad [\text{volume/mass}]$$

$$CWU_{green} = 10 \times \sum_{d=1}^{l_{gp}} ET_{green} \quad [\text{volume/area}]$$

$$WF_{proc,blue} = \textit{BlueWaterEvaporation} + \textit{BlueWaterIncorporation} + \textit{LostReturnflow}$$

[volume/time]

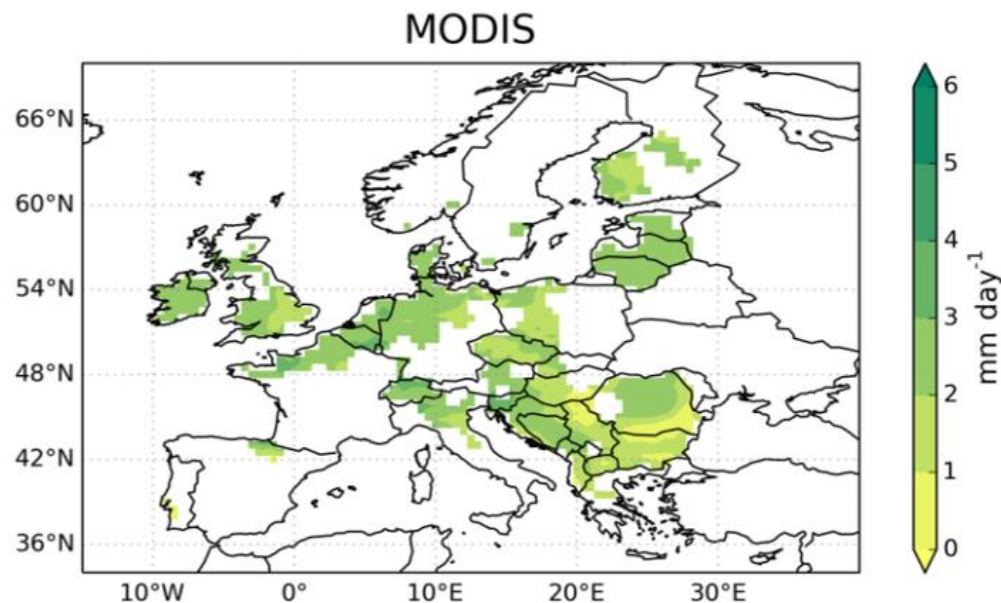

$$WF_{proc,blue} = \frac{CWU_{blue}}{Y} \quad [\text{volume/mass}]$$

$$CWU_{blue} = 10 \times \sum_{d=1}^{l_{gp}} ET_{blue} \quad [\text{volume/area}]$$

Green and Blue water footprint

Green and Blue water consumption are mapped based on the available climate and rainfall models as well as models determining the required amount of water to grow a certain crop.

- Modelling Evapotranspiration (ET) ($ET = WF_{Green}$)
- Evaluate model at regional & global scales
 - Data sets used: FLUXNET-MTE, GLEAM, MODIS
- Precipitation maps
- $WF_{Blue} = ET_{max\ yield} - Precipitation$

Water footprinting Calculations

$$WF_{proc, grey} = \frac{L}{c_{max} - c_{nat}} \quad [\text{volume/time}]$$

$$WF_{proc, grey} = \frac{(\alpha \times AR) / (c_{max} - c_{nat})}{Y} \quad [\text{volume/mass}]$$

Grey water factors

Grey water footprint

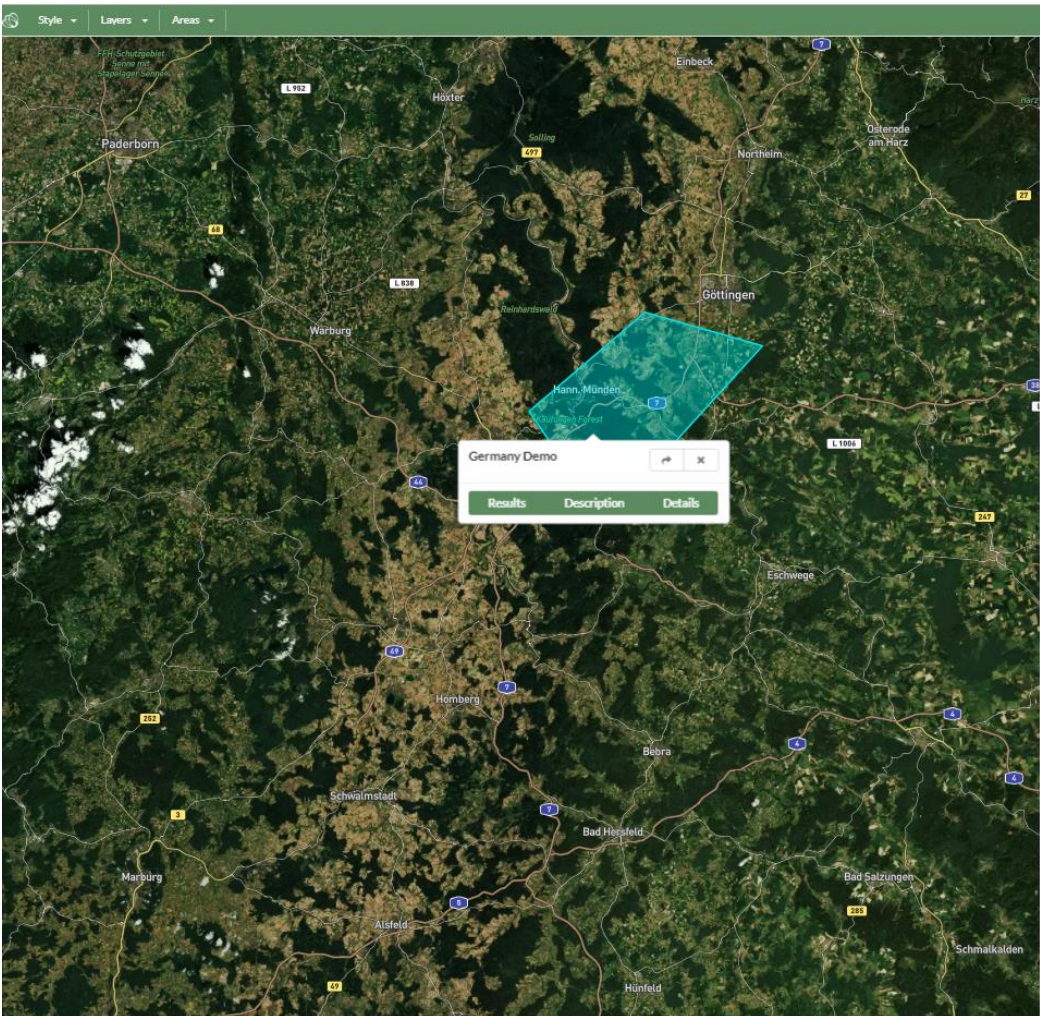

Grey water consumption is calculated based on mapped and submitted impact factors and the Grey Water Model by Franke et al. (2013)

- $GWF = (\alpha * Appl) / (c_{max} - c_{nat})$
 - α – Grey water factors weighted intensity
 - Appl – Application of chemical – user
 - c_{max} – Maximal contamination – maps
 - c_{nat} – Natural contamination – maps

Grey water is the amount of water necessary to assimilate contaminated water (A.Y. Hoekstra, 2012)

Göttingen area - Germany

Green Water Footprint - Winter Wheat

75.0 m3 tonne-1

The Green Water Footprint is the consumed rainfall required for agriculture (here for growing winter wheat).

The green component of crop water use was simulated by a crop model (ACM-GPP-ET modelTM) for Europe at 0.5 degrees resolution. The actual evapotranspiration (ET), which is the sum of the water evaporated from the soil or crop surface and transpired from crops (i.e. the water required for crop growth), was measured for each month over Europe for winter wheat. Finally this Green Water Footprint dataset (m3 tonne-1) was calculated as actual ET (in m3 ha-1) divided by the crop yield (tonne ha-1).

This Green Water Footprint data was one of the products developed by the University of Edinburgh as part of the Global Water Footprint pilot study funded by the DataLab, in partnership with Ecometrica.

TMACMET-GPP-ET model: Aggregated Canopy Model-Gross Primary Productivity-Evapotranspiration version 1

Blue Water Footprint - Winter Wheat

-0.5 m3 tonne-1

The Blue Water Footprint corresponds to the surface and groundwater sources used for irrigation for agriculture (here for growing winter wheat).

Water deficits in crop production are usually solved by increasing irrigation (i.e. adding Blue Water). On global scales, green water use is ~4 to 5 times greater than blue water use. The blue component of crop water use was simulated by a crop model (ACM-GPP-ET modelTM) for Europe at 0.5 degrees resolution. The actual evapotranspiration (ET), which is the sum of the water evaporated from the soil or crop surface and transpired from crops (i.e. the water required for crop growth), was measured for each month over Europe for winter wheat. This Blue Water Footprint dataset was calculated by subtracting the actual ET (which is limited by the amount of available water) from the potential ET (maximum ET if there is no water limitation).

This Blue Water Footprint data was one of the product developed by the University of Edinburgh as part of the Global Water Footprint pilot study funded by the DataLab, in partnership with Ecometrica.

TMACMET-GPP-ET model: Aggregated Canopy Model-Gross Primary Productivity-Evapotranspiration version 1

Calculating emissions from Land Use and Land Use Change (LULUC)

Why calculate emissions from land use and land use change?

- *Reporting requirement for countries obligated to submit a National Greenhouse Gas Inventory (Annex I party to the UNFCCC)*
- *LCA of land-based products (e.g. biofuels, crops, meat)*
- *Understand impact of deforestation and other primary vegetation loss*

United Nations
Climate Change

Current calculation method

- Guidance, methods, calculation steps and default emission factors provided in Volume 4 (AFOLU) of the IPCC guidelines
- Considers (i) changes in carbon stock in biomass, dead wood, litter and soils
(ii) GHG emissions due to land management activities (fire, fertiliser, livestock, flooding)
- Requires background reading and understanding, multiple worksheets and complicated calculation steps
- Specific emission factors may need time consuming research

EQUATION 2.8

ANNUAL CHANGE IN CARBON STOCKS IN BIOMASS
IN LAND REMAINING IN THE SAME LAND-USE CATEGORY (STOCK-DIFFERENCE METHOD)

$$\Delta C_B = \frac{(C_{t_2} - C_{t_1})}{(t_2 - t_1)} \quad (a)$$

where

$$C = \sum_{i,j} \{A_{i,j} \cdot V_{i,j} \cdot BCEF_{S_{i,j}} \cdot (1 + R_{i,j}) \cdot CF_{i,j}\} \quad (b)$$

LULUC Analysis Steps on the Ecometrica Platform

Step 1: Add a 'test' area with available sequential land use maps to the Ecometrica platform (Marques de Comillas, Chiapas, Mexico)

Step 2: Perform additional analysis to re-classify original datasets into the 6 IPCC categories (Forest Land, Cropland, Grassland, Wetlands, Settlements, Other Land)

Step 3: Determine the areas of land covered by each category, and land areas converted from one category to another between two periods

Step 4: Input the area data to the calculation steps

Step 5: Select appropriate activities which will automatically select the proper emissions factors (IPCC defaults and regionally specific factors)

Step 6: Calculate emissions automatically on the platform according to the IPCC Volume 4 (AFOLU)

Step 7: Display results on the Ecometrica platform

LULUC questions and activities

The screenshot shows the 'ecometrica' logo and 'LULUC Test' header. A status bar indicates 'Data Entry - 6/7 completed'. A sidebar on the left lists categories: 'Cropland remaining cropland' (4/4), 'Forest land remaining forest land' (2/2), and 'Land converted to cropland' (0/1). The main area displays a question titled 'Mineral soil carbon stock (reporting year)' with instructions to select soil type, land use, and tillage regime, and enter the area of land.

Select the IPCC land conversion category

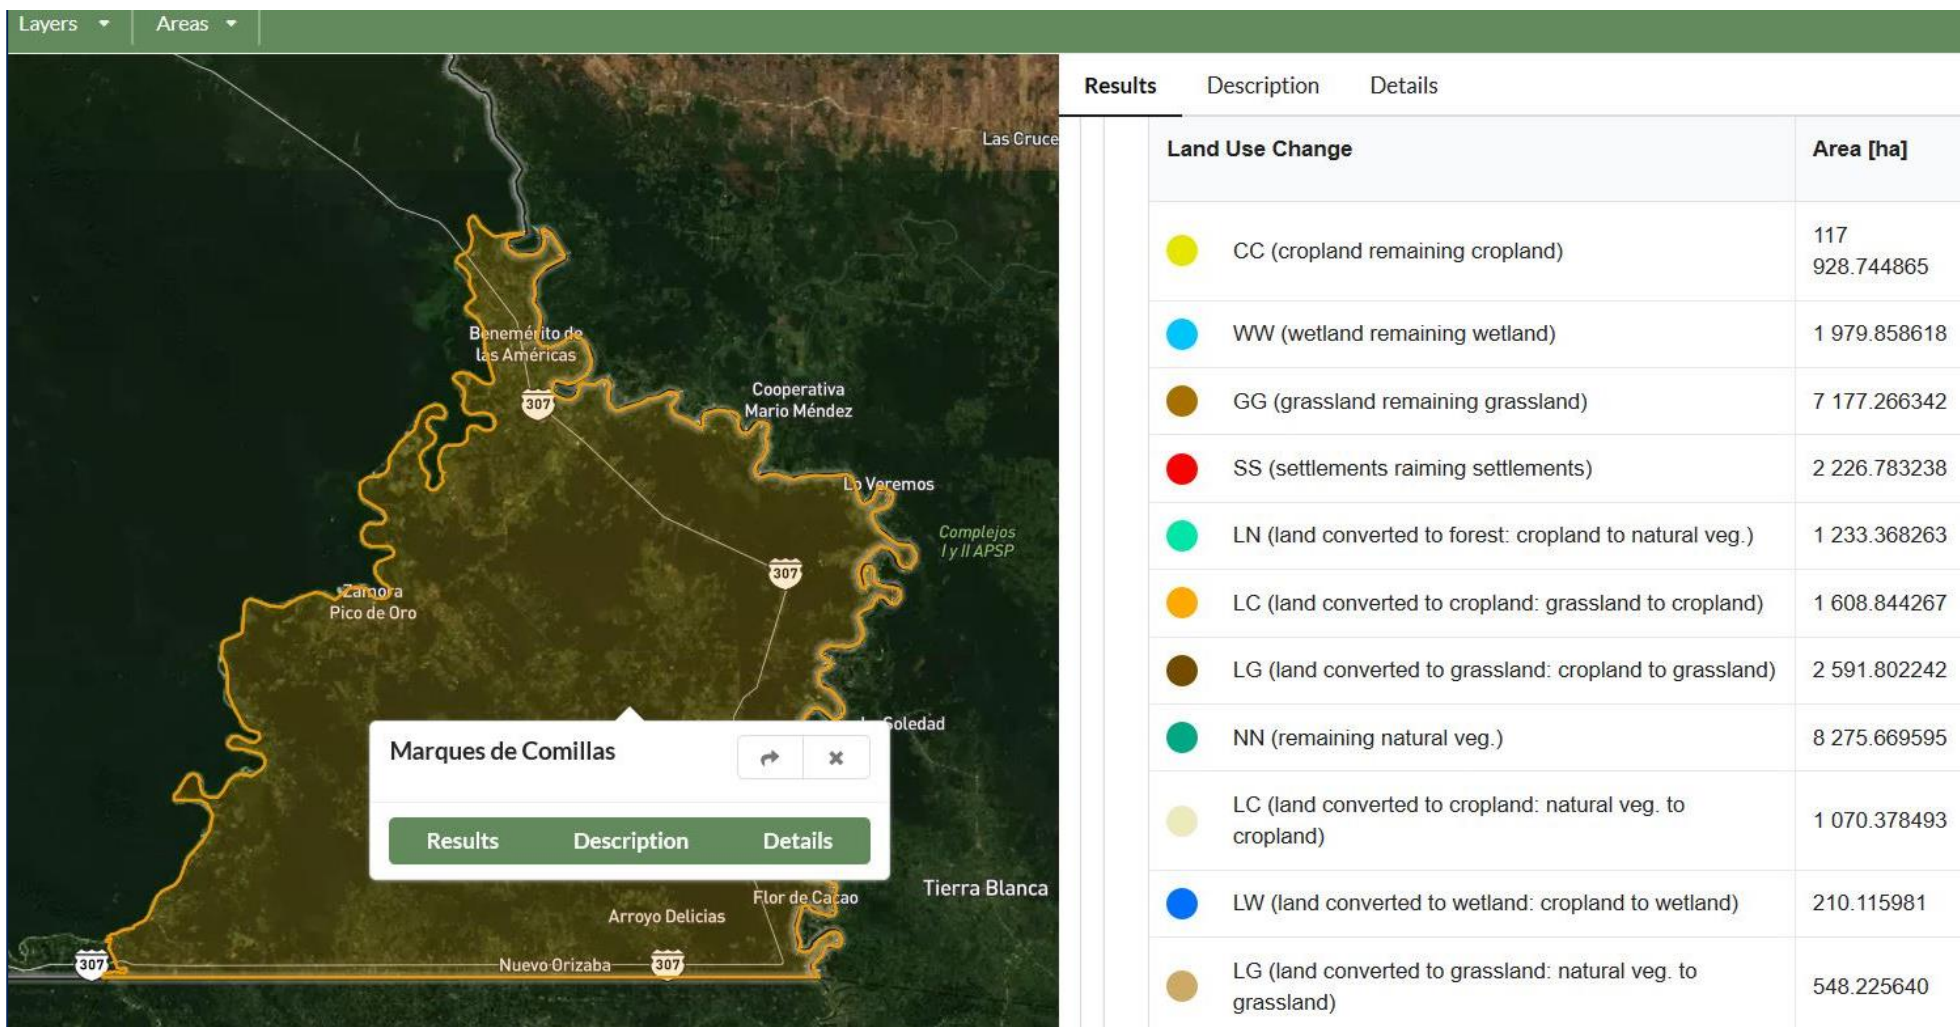

Questions relating to relevant changes in carbon stock for that category are added

Three overlapping question cards are shown. The top card is 'Mineral soil carbon stock (reporting year)', the middle is 'Mineral soil carbon stock (initial/reference year)', and the bottom is 'Above ground biomass - carbon loss due to harvesting'. Each card includes an 'Add Answer' button and an 'Exclude Question' button.

This screenshot shows a question titled 'Above ground biomass - carbon loss due to wood removal'. The question text asks to select the type of forest and enter the area harvested. The input fields show '678', 'Cubic Metre', and 'Jan 1, 2015 - Dec 31, 2015'. Below the question, there is an 'Unanswered' status and an 'Activity' dropdown menu. The dropdown menu lists several options for wood removal from humid tropical natural forest, categorized by area (e.g., <10m3, 21-40m3, 41-60m3, 61-80m3, 81-120m3, 120-200m3, >200m3).

Multiple options 'activities' available under each question, each activity links to a geographically relevant emission factor
