Global Surface Water Explorer

Pixel based classifier

A globally consistent and validated dataset documenting the different facets of the water **dynamics** and its changes.

A virtual time machine that maps the location and temporal distribution of water surfaces at the **global scale** over the past 3.7 decades, and provides statistics on their extent and change to support better informed water-management decision-making.

Each pixel of the **4,185,439** Landsat scenes was classified as water, land or non-valid observation

High-resolution mapping of global surface water and its long-term changes

Jean-François Pekel¹, Andrew Cozzari¹, Noel Gorelick² & Alan S. Belward¹

The location and persistence of surface water (inland and coastal) is both affected by climate and human activity¹ and affects climate^{2,3}, biological diversity⁴ and human well-being^{5,6}. Global data sets documenting surface water location and seasonality have been produced from inventories and national descriptions⁷, statistical extrapolation of regional data⁸ and satellite imagery^{9–12}, but measuring long-term changes at high resolution remains a challenge. Here, using three million Landsat satellite images¹³, we quantify changes in global surface water over the past 32 years at 30-metre resolution. We record the months and years when water was present, where occurrence changed and what form changes took in terms of seasonality and persistence. Between 1984 and 2015 permanent surface water has disappeared from an area of almost 94,000 square kilometres, roughly equivalent to that of Lake Superior, though new permanent bodies of surface water covering 184,000 square kilometres have formed elsewhere. All continental regions show a net increase in permanent water, except Oceania, which has a fractional (one per cent) net loss. Much of the increase is

from reservoir filling, although climate change¹⁴ is also implicated. Loss is more geographically concentrated than gain. Over 70 per cent of global net permanent water loss occurred in the Middle East and Central Asia, linked to drought and human actions including river diversion or damming and unregulated withdrawal^{15,16}. Losses in Australia¹⁷ and the USA¹⁸ linked to long-term droughts are also evident. This globally consistent, validated data set shows that impacts of climate change and climate oscillations on surface water occurrence can be measured and that evidence can be gathered to show how surface water is altered by human activities. We anticipate that this freely available data will improve the modelling of surface forcing, provide evidence of state and change in wetland ecotones (the transition areas between biomes), and inform water-management decision-making.

Between any two points in time, part of the Earth's surface is invariably underwater and part is never underwater, with the remainder fluctuating between these extremes. Coastlines and lake and river boundaries advance and retreat, rivers meander, new permanent lakes form and

Some Applications

1. Sustainable Development Goal (SDG) 6.6.1 - tracks changes in water-related ecosystems - *Freshwater Ecosystems Explorer*, www.sdg661.app)
2. Monitor reservoirs all around the world in terms of changes in their surface extent, and identification of new reservoirs;
3. Statistics about measurable changes in the extent of permanent and seasonal surface water bodies in cropland areas. “*State of the world’s land and water resources for food and agriculture (SOLAW 2021)*” - *Food and Agriculture Organization (FAO)*

SDG 6.6.1

By 2020, protect and restore water-related ecosystems, including mountains, forests, wetlands, rivers, aquifers and lakes

Freshwater Ecosystem Explorer (www.sdg661.app)

The Freshwater Ecosystem Explorer is a free and easy-to-use data platform. It provides accurate, up-to-date, high-resolution, geospatial data concerning the extent, freshwater ecosystems change over time.

By helping decision-makers understand dynamic ecosystem changes, the data presented on this open access platform is intended to drive action to protect and restore freshwater ecosystems and establish metrics to track progress towards the achievement of Sustainable Development Goal Target 6.6. Data can be visualized and downloaded at national, sub-national and basin levels. Data is available for the following:

- Permanent & Seasonal Surface Waters | Reservoirs | Wetlands | Mangroves | Water Quality

Also available in Spanish, French, Italian, German, Portuguese, Russian, Arabic, Hindi, Chinese, Japanese, Korean, Vietnamese, Thai, Indonesian, and Urdu.

Indicator 6.6.1 (Tier I Indicator) “Change in the extent of water-related ecosystems over time “

Changes in the extent of surface water bodies in cropland areas (FAO – SOLAW 2021)

We computed the change in permanent and seasonal surface water bodies extent on irrigated and rainfed cropland using GSWE historical data

www.fao.org/land-water/solaw2021/en

Conclusions

- GSWE supports applications including water resource management, climate modelling, biodiversity conservation and food security, and facilitates the exact quantification of the extent and dynamics of inland water bodies.
- The GSWE dataset was officially endorsed by the United Nations as the official indicator for monitoring progress towards SDG target 6.6 (Ecosystems)
